

What is a microgrid digital twin?

A microgrid digital twin (MGDT) refers to the digital representation of a microgrid(MG),which mirrors the behavior of its physical counterpart by using high-fidelity models and simulation platforms as well as real-time bi-directional data exchange with the real twin.

What is a digital twin?

The digital twin (DT) concept opens a new dimension in the energy system to break down data silos and carry out seamless functional processes in data analysis, modeling, simulation, and artificial intelligence (AI)-driven decision-making.

Why do we need converters for microgrids?

As a result, converters are critical to developing microgrids, and, therefore, special attention must be paid to them. The use of data-driven approaches and digital twin models can solve various challenges relating to power electronic equipment, such as device faults, health conditions, remaining life, optimisation and control.

What is the DT of microgrid components?

Summary of the DT of Microgrid Components. Generally, the simulation studies and modelling on grid-connected microgrids are carried out considering physics-based, data-driven and hybridisation modelling techniques. These models are available on simulation platforms, such as MATLAB Simulink and Real Time Digital Simulator (RTDS).

How to build a modern microgrid?

To build modern microgrids, it is necessary to enable them to function as a real-time monitoring and controllable unit with three important advantages: Flexible to accommodate advanced digital technologies and digest the uncertainties of the grid edge to form a scalable cyber-physical network.

Does a grid-connected microgrid impact the rest of the power system?

The simulation study on the impact of the operation of a grid-connected microgrid on the rest of the power system network does not mimic the real-world scenario due to the utilisation of a fixed microgrid model. The MGDT can address this challenge as it is considered to be closer to the real-world scenario.
